

4th International Conference on

DEMENTIA AND DEMENTIA CARE

December 04-05, 2023 | Dubai, UAE

Dementia care

Eric Brian

School for Advanced Studies in the Social Sciences, France.

Historically, statistical variance has been defined as the average of the squared differences between the previously computed variable mean under consideration and each of the values of this variable. This is the usual variance. It can be shown that the average of all the squared differences between two individual values is equal to the usual variance, as far as all the pairs of cases being compared are given the same weight.

The basis of the presentation, a mathematical article published in 2017, proposes to consider an extension

of variance according to the principle of not uniform but varied weights for the pairs of cases compared in the calculation. Practically, such a variability may come from the external world (for example: on a map of administrative divisions, differences between neighbouring districts can be overlooked) but it may also come from the mental interiority of subjects in a situation, more or less inclined as they may be not to take every combination of cases into consideration, or only considering some among them. The presentation will outline some extensions of this reasoning in sociology and cognitive science.

Biography

Éric Brian is a historian of science and a sociologist. He studies the uncertainty and regularity of social phenomena, and in particular, how scientists have caught and conceived them as objects of mathematics or social and economic sciences. He is currently senior professor at EHESS (École des hautes études en sciences sociales, Paris, France). Since 1995, he has been the editor of the *Revue de synthèse* today published at Brill Publishers (Paris). Between 1997 and 2018, he taught at the University of Vienna (Austria).
