Pregnancy after supracervical hysterectomy: A case report from Hanoi Obstetrics and Gynecology Hospital and literature review

Toan Khac Nguyen, Hai Xuan Nguyen and Duy Anh Nguyen
Hanoi Obstetrics and Gynecology Hospital, Vietnam

Pregnancy after hysterectomy is one of the most uncommon conditions in modern medicine. Since the first reported case in 1895, there have been merely 40 cases described. Post-hysterectomy pregnancy diagnosis is not often entertained due to its unusualness which leads to delayed remedy and in some cases, life-threatening or catastrophic conditions. In this article, a case of a 40-year-old multigravida woman having a pregnancy in the left fallopian tube 3 years after a supra-cervical hysterectomy at Hanoi Obstetrics and Gynecology Hospital was described. The patient underwent a successful laparoscopic intervention and was discharged after 3 days of postoperation. A brief review of literature is also discussed.

Biography

Toan Khac Nguyen is an Obstetrician and Gynecological Surgeon currently working at the Hanoi Obstetrics and Gynecology Hospital. He is also pursuing his Doctoral studies from University of Tartu, Estonia and the University of Helsinki, Finland.
