Description

Respiratory health problem is one of the major health problem among bricks assiduity workers those who are working in fine area. These problem can be reduce when proper intervention taken like use of mask, kerchief and other bias during working time. The bricks assiduity is one of the traditional assiduities giving work to huge number of semiskilled and untalented sloggers. This manufacturing has been taking interest in product of colorful products like concave bricks, country bricks, concave block bricks and fly ash bricks. In structure conditioning in civic and pastoral areas has further encouraged this assiduity to have its stake in the request. The brick timber process includes burrowing, forming, and mounding, mounding and evacuating, terminating of blocks and transportation of blocks to the normal thing. Every one of these procedures includes unskilled workers. Workers at slipup kiln might connected with conveying complexion dust and bricks, molding or baking release from slipup kilns contains bitsy dust patches, hydrocarbons, oxides of nitrogen, carbon monoxide, fluoride composites and limited volume of carcinogenic dioxins if rubber tires were employed. Complexion dust include a mix of on-living emulsion including silica, lime, magnesium carbonate, iron oxide, alkalis, calcium sulfate, calcium carbonate and sodium chloride and changeable quantum of organic accoutrements.

Quartz Gemstone

Utmost of the slipup kiln use forestland and coal for boiling the bricks that make the slipup kiln people at threat to high exposure to air pollution and it has an adverse health effect on the workers. Due to air

pollution at the kiln, a significantly advanced proportion of casket characteristic conditions have been plant among slipup kiln workers compare to the general population [5]. One of the major pitfalls of slipup dust inhalation is liquid silica exposure. Silica is generally seen in quartz gemstone and minerals when cut, crushed and ground, patches small sufficient to breathe are released into the air. As a known carcinogen, long duration of inhalation of crystalline silica can drop the breathing capability of the lungs. The study concludes that respiratory health problem is more common in bricks worker. The significance of the exploration process to assess respiratory health status of bricks workers. This information was collected through questionnaire and interpreted by applying descriptive and deducible statistical system. Result showed that factors like times of experience, habits of smoking, age are more responsible for respiratory health problem among bricks workers.

Age Estimation

Age estimation in the living is one of the most important tasks especially in developing countries where both birth records are frequently not available or not well-maintained. Despite the fact that there are a number of laws taking enrollments of births most births are not duly recorded. Though there are numerous general experimental factors in assessing the age, changes in bones especially time affiliated appearance and emulsion of different ossification centers in growing period are precious indicators for assessing the age 4. The variation in the appearance and the emulsion of ossification centers is substantially attributed to colorful factors like climate, heritable, race, nutrition, salutary habits and gender, socioeconomic status of the population. Scientific estimation of age of an individual whether living or dead or from mortal remains is a vexing problem for medical magistrate in both civil and felonious matters, age estimation cases are frequently appertained to forensic experts as it plays a vital part in deciding upon the amount of discipline given to the indicted and where to execute the same in a reformation or juvenile court academy or jail. As the age between times is veritably important medico legally especially in the ladies, it's important to separate between in employment and in connection with Hindu marriage act. Amongst all the parameters of age determination, radiological examination of bones ends has shown delicacy and trust ability respectable to medical profession and legal fraternity. So the ideal of this study is the to find out the age of an individual from the emulsion of secondary ossification centers around elbow joint and Wrist joint, to compare the age of emulsion of ossification centers around elbow and wrist joints between males and ladies.
