

Comparison of the Hypoproteinemic Capacities of Erythropoietin and U-74389G

Tsompos C^{1*}, Panoulis C², Toutouzas K³, Triantafyllou A⁴, Zografos CG³ and Papalois A⁵

Abstract

Aim: This study compared the hypoproteinemic effects of erythropoietin (Epo) and antioxidant drug U-74389G based on 2 preliminary studies. The provided results at serum total protein (TP) levels decline were co-evaluated in a hypoxia reoxygenation protocol of an animal model.

Materials and methods: TP levels were evaluated at the 60th reoxygenation min (for groups A, C and E) and at the 120th reoxygenation min (for groups B, D and F) in 60 rats. Groups A and B received no drugs, rats from groups C and D were administered with Epo; whereas rats from groups E and F were administered with U-74389G.

Results: The first preliminary study recommended a hypoproteinemic effect of Epo (p-value=0.4430). The second preliminary study proved the hypoproteinemic effect of U-74389G (p-value=0.0005). These 2 studies were co-evaluated since they came from the same experimental setting. The outcome of the co-evaluation was that U-74389G has at least 4-fold hypoproteinemic action than Epo (p-value=0.0000).

Conclusions: The neurologist must take into consideration the powerful hypoproteinemic effect of the 2 drugs; mainly that of U-74389G whether implicated in neurological diseases.

Keywords

Hypoxia; Erythropoietin; U-74389G; Total protein; Reoxygenation

Introduction

The short-term hypoproteinemic [1] action of U-74389G is significant (p-value=0.0005). U-74389G is a novel antioxidant factor. It implicates just only 255 known biomedical studies at present. 4.31% of these studies concern tissue hypoxia and reoxygenation (HR) experiments. The promising effect of U-74389G in tissue protection has been noted in these HR studies. U-74389G or also known as 21-[4-(2,6-di-1-pyrrolidinyl-4-pyrimidinyl)-1-piperazinyl]-pregna-1,4,9(11)-triene-3,20-dione maleate salt is an antioxidant which prevents both arachidonic acid-induced and iron-dependent lipid peroxidation. It protects against HR injury in animal heart, liver and kidney models. These membrane-associating antioxidants are

Received: December 15, 2017 Accepted: December 20, 2017 Published: December 27, 2017

particularly effective in preventing permeability changes in brain micro vascular endothelial cells monolayers. The biochemical capacities of U-74389G were summarized as Na⁺, K⁺, Mg²⁺-ATPase inhibition in the perihematoma basal ganglia territory; cholinergic response enhancement; membrane-bound enzymes stabilization; 3,4-dihydroxyphenylacetic acid (DOPAC) activity increase in the ipsilateral striatum of oligemic nigrostriatal system; antiapoptotic properties prove; caspase-3 immunoreactivity down-regulation; local cerebral extracellular superoxide anion concentrations reduce; 2,3-DHBA levels and the excitatory amino acid attenuation in hippocampus; brain total sulfhydryl groups levels restoration to normal values and the oxidant peroxynitrite consumption attenuation produced by brain microglia. However, the hypoproteinemic capacity of U-74389G gets more comprehensible whether is compared with the same capacity of a standard known drug. Such one of the more well studied drug; whereas without significant hypoproteinemic [2] action (p-value=0.4430) is erythropoietin (Epo). Actually, Epo implicates over 30,162 known biomedical studies at present. 10.41% at least of these studies concern tissue hypoxia and reoxygenation (HR) experiments. Certainly, the concept has been moved away from the original action of Epo in stem blood cells recovery. However, just few related reports were found, not covering completely the specific matter with total protein.

The special aim of this experimental work was to compare the hypoproteinemic effects of U-74389G and Epo on a rat model and mainly in an HR protocol. Their effects were tested by measuring the serum mean total protein (TP) levels.

Materials and Methods

Animal preparation

The Vet licenses of the research were provided under 3693/12-11-2010 & 14/10-1-2012 decisions. The granting company and the place of the experiment are mentioned in related references [1,2]. Accepted standards of humane animal care were adopted for Albino female WISTAR rats. 7 days pre-experimental normal housing included *ad libitum* diet in laboratory. Continuous intra-experimental anesthesiologic techniques, oxygen supply, electrocardiogram and acidometry were provided. Post-experimental awakening and preservation of animals was not permitted, even if euthanasia was needed. Rats 16-18 weeks old were randomly delivered to four (6) groups (n=10), using the following protocols of HR: Hypoxia for 45 min followed by reoxygenation for 60 min (group A); hypoxia for 45 min followed by reoxygenation for 120 min (group B); hypoxia for 45 min followed by immediate Epo intravenous (IV) administration and reoxygenation for 60 min (group C); hypoxia for 45 min followed by immediate Epo IV administration and reoxygenation for 120 min (group D); hypoxia for 45 min followed by immediate U-74389G intravenous (IV) administration and reoxygenation for 60 min (group E); hypoxia for 45 min followed by immediate U-74389G IV administration and reoxygenation for 120 min (group F). The dose height selection criteria of Epo and U-74389G were assessed at preliminary studies as 10 mg/Kg body mass of animals for both drugs.

Hypoxia was caused by laparotomic clamping inferior aorta over renal arteries with forceps for 45 min. Reoxygenation was induced

by removing the clamp and restoration the inferior aorta patency. After exclusion of the blood flow, the protocol of HR was applied, as described above for each experimental group. The drugs were administered at the time of reperfusion; through catheterized inferior vena cava. The TP levels were determined at 60th min of reoxygenation (for A, C and E groups) and at 120th min of reoxygenation (for B, D and F groups). The TP values used were adjusted for rats' mass since a powerful relation was invented between them (p-value=0.0000).

Statistical analysis

Table 1 presents the (%) decreasing influence of Epo regarding reoxygenation time. Also, Table 2 presents the (%) decreasing influence of U-74389G regarding reoxygenation time. Chi-square test was applied using the ratios which produced the (%) results per endpoint. The outcomes of chi-square tests are depicted at Table 3. The statistical analysis was performed by Stata 6.0 software [Stata 6.0, StataCorp LP, Texas, USA].

Discussion

Barbierato et al. [3] promoted progression, morphological development and maturation of undifferentiated oligodendrocyte precursor cells into a more differentiated phenotype and TP content without affecting proliferation; although oligodendrocytes have limited ability to repair the damage to themselves or to other nerve cells, as seen in demyelinating diseases like multiple sclerosis. Tan et al. [4] ascribed the exhibited remarkable presynaptic neurotoxicity presumably to the action of neurotoxic basic phospholipases A2 in high abundance (35% of TP abundance) from a total of 11 different protein families in the venom proteome content of Sri Lankan *Mitragyna speciosa* Korth ketum. Perez et al. [6] quantified butyrylcholinesterase specific activity and its inhibition by the nerve agents' sarin and VX; normalized to the TP content in a robust dried spot activity assay sample more resistant to

degradation. Wang et al. [7] greatly decreased the TP expression of 5 α -reductase inhibitor dutasteride mediating maximal contraction of the whole ventral prostate. Navarro et al. [8] noticed that protracted abstinence from alcohol increased the dendritic arborization within apical dendrites of pyramidal neurons; the stress sensitivity and hypothalamic-pituitary-adrenal axis dysregulation. Stress altered oligodendrocyte expression as a hypophosphorylation of the glucocorticoid receptor at Ser-232 without affecting expression of TP in rodents and promoted hypermyelination in the medial prefrontal cortex in alcohol dependent subjects. Kaur et al. [9] associated nerve tissue TP samples with chronic constriction injury of sciatic nerve induced neuropathic pain amelioration after ramipril (angiotensin-converting enzyme inhibitor) administration. Hübler et al. [10] could not correlate TP plasma concentrations and ropivacaine local total and free concentrations after psoas compartment block, especially whether combined with sciatic nerve block. Liu et al. [11] remarked the significant anti-bacterial and PO activities alterations of the TP extract after enkephalinergic neurotransmitter [Met(5)]-enkephalin incubation which firstly observed on the marginal of the dorsal half; indicated that this released by nervous system was firstly appeared, while the primitive immune defense system existed in the region of prototroch and developed maturely in trochophore, D-hinged and umbo larvae of oyster *Crassostrea gigas*. Sánchez-González et al. [12] measured plasma levels of TP in manganese (Mn) excess neurotoxicity CRF patients. Salvarani et al. [13] associated greater cerebrospinal fluid TP concentrations with bioptic diagnosis of uncommon condition (2.4 cases per 1,000,000 person-years) of primary central nervous system vasculitis in which lesions are limited to vessels of the brain and spinal cord than angiographic diagnosis. Perga et al. [14] replaced the TP content by the three protein spots method in order to subdivide the multiple sclerosis patients. Kannan et al. [15] quantified the maximum expression of a 48 kDa Pax6 transcription factor involved in vertebrate eye, brain and central nervous system formation during early embryonic and larval development or embryogenesis at 8 hours post fertilization as 179ng/embryo from the

average TP of 9.5µg/embryo in zebra fish model system. Shibasaki et al. [16] significantly related serum TP with inpatient pre-rehabilitation FIM score and Barthel index investigating the utility of sympathetic nervous activity after treatment of acute phase illness in frail elderly patients 75 years or older. Schmid et al. [17] argued against an autochthonous production in the central nervous system due to the positive correlation between the human cerebrospinal fluid (CSF)/serum ratios for adipsin and TP. Patients suffering from infectious diseases had higher CSF levels of adipsin than multiple sclerosis patients. Koie et al. [18] correlated the 5-year biochemical recurrence-free survival rate with preoperative serum butyrylcholinesterase - an alpha-glycoprotein found in the nervous system - levels (P<0.001) for prostate cancer after radical prostatectomy. Ligtenberg et al. [19] found increased salivary flow rate and protein secretion after sympathetic stimuli such as physical exercise (p<0.01). Yu et al. [20] associated TP with long-term prognosis in decompressive craniectomy group in severe traumatic brain injury treatment. Yao et al. [21] modulated the enteric nervous system and intestinal motility influencing malodorous flatus, irritable bowel syndrome, ulcerative colitis and prevention of colorectal cancer by harmful metabolites of increased protein fermentation due to high-TP intake or specifically, aromatic and sulphur-containing amino acids. Wang et al. [22] found that nitric oxide induces cysteine S-nitrosylation of TP which decrease the vesicular neurotransmitter uptake such as monoamines, acetylcholine and glutamate, in synaptosomes of the central nervous system. Kuznetsova et al. [23] revealed high stability of TP level in healthy children but significant individual deviations from the average TP value in children with nervous system dysfunction. Da Silva et al. [24] demonstrated significant increases in parasymphathetic related indices and TP levels after 17 weeks ballet training period. Li et al. [25] manifested markedly increased levels of CSF TP and diffuse spinal Dura matter thickening in hypertrophic spinal pachymeningitis associated with rare myeloperoxidase-antineutrophil cytoplasmic antibody (MPO-ANCA) localized exclusively in the spine.

The above biochemical capacities of U-74389G present beneficial properties such as neuroprotection, inflammatory responses counteraction; post IR cerebral edema and neuronal necrosis decline in a hippocampal subfield; apoptotic cell death and sub-sequent cortical infarction prevention, final lesion decrease; late learning impairments prevention after intrastriatal administration; anoxic terminal negativity (ATN)-latency spikes decline in hippocampal

region; epileptogenic discharges reduce; hippocampal damage prevention; living pyramidal neurons increase; potential early forms of Alzheimer's disease treatment.

Epo effect was summarized in increasing glomerular filtration leakage of constant ratio both renal Epo and TP excretion reaching up to 23% of the administered high-dose rEpo due to lower kidneys maturation; considering potent neuroprotection in brain injury encephalopathy of preterm infants and improving the nutritional status (TP levels) of patients after alteration from maintenance hemodialysis (HD) to CAPD 6 months treatment program. Furthermore, Hirata et al. [26] delayed end-stage kidney disease by a single dose of epoetin β pegol (continuous erythropoietin receptor activator (CERA) given on day 1, alleviating increasing urinary TP in a rat model of chronic kidney disease. Hypoxia-inducible factors (HIFs) are transcription factors that respond to decreases in available oxygen in the cellular environment, or hypoxia [27]. In normal circumstances after injury HIF-1α is degraded by prolyl hydroxylases (PHDs). The continued up-regulation of HIF-1α via PHD inhibitors regenerates lost or damaged tissue in mammals that have a repair response; and the continued down-regulation of Hif-1α results in healing with a scarring response in mammals with a previous regenerative response to the loss of tissue. The act of regulating HIF-1α can either turn off, or turn on the key process of mammalian regeneration [28]. The HIF stabilization using an HIF prolyl-hydroxylase inhibitor enhances hippocampal memory, likely by increasing erythropoietin expression. HIF pathway activators such as ML-228 may have neuroprotective effects and are of interest as potential treatments for stroke and spinal cord injury.

As mentioned above, Table 3 shows that U-74389G has at least 4-fold hypoproteinemic capacity than Epo (p-value=0.0000). This has a dual biochemical interpretation. Epo may contribute with some of its anabolic capacities or the antioxidant capacities of U-74389G are very protein consuming. A meta-analysis of these ratios from the same experiment, for 10 other seric variables, provides comparable results (Table 4).

Conclusion

The neurologist must be informed about the hypoproteinemic effects whether treats patients receiving Epo but mainly U-74389G. Epo expression enhances hippocampal memory; whereas HIF

Table 4: A U-74389G / erythropoietin efficacies ratios meta-analysis on 10 hematologic variables (4 variables with balancing efficacies and 2 variables with opposite efficacies) [29].
